## **SQL** Cheat Sheet: Accessing Databases using Python

## **SQLite**

Topic	Syntax	Description	Example
connect()	sqlite3.connect()	Create a new database and open a database connection to allow sqlite3 to work with it. Call sqlite3.connect() to create a connection to the database INSTRUCTOR.db in the current working directory, implicitly creating it if it does not exist.	<pre>1. 1 2. 2 1. import sqlite3 2. con = sqlite3.connect("INSTRUCTOR.db") Copied!</pre>
cursor()	con.cursor()	To execute SQL statements and fetch results from SQL queries, use a database cursor. Call con.cursor() to create the Cursor.	<pre>1. 1 1. cursor_obj = con.cursor() Copied!</pre>
execute()	cursor_obj.execute()	The execute method in Python's SQLite library allows to perform SQL commands, including retrieving data from a table using a query like "Select * from table_name." When you execute this command, the result is obtained as a collection of table data stored in an object, typically in the form of a list of lists.	<pre>1. 1 1. cursor_obj.execute('''insert into INSTRUCTOR values (1, 'Rav', 'Ah</pre>
fetchall()	cursor_obj.fetchall()	The fetchall() method in Python retrieves all the rows from the result set of a query and presents them as a list of tuples.	<pre>1. 1 2. 2 3. 3 4. 4 5. 5  1. statement = '''SELECT * FROM INSTRUCTOR''' 2. cursor_obj.execute(statement) 3. output_all = cursor_obj.fetchall() 4. for row_all in output_all: 5. print(row_all)</pre>
fetchmany()	cursor_obj.fetchmany()	The fetchmany() method retrieves the subsequent group of rows from the result set of a query rather than just a single row. To fetch a few rows from the table, use fetchmany(numberofrows) and mention how many rows you want to fetch.	<pre>3. 3 4. 4 5. 5  1. statement = '''SELECT * FROM INSTRUCTOR''' 2. cursor_obj.execute(statement) 3. output_many = cursor_obj.fetchmany(2)</pre>
read_sql_query(	() read_sql_query()	read_sql_query() is a function provided by the Pandas library in Python, and it is not specific to MySQL. It is a generic function used for executing SQL queries on various database systems, including MySQL, and retrieving the results as a Pandas DataFrame.	<pre>1. 1 1. df = pd.read_sql_query("select * from instructor;", conn) Copied!</pre>
shape	dataframe.shape	It provides a tuple indicating the shape of a DataFrame or Series, represented as (number of rows, number of columns).	<ol> <li>1. 1</li> <li>1. df.shape</li> </ol> Copied!
close()	con.close()	con.close() is a method used to close the connection to a MySQL database. When called, it terminates the connection, releasing any associated resources and ensuring the connection is no longer active. This is important	1. 1 1. con.close()  Copied!
